

**ALGORITHM 59**
**ZEROS OF A REAL POLYNOMIAL BY RESULTANT  
PROCEDURE**

E. H. BAREISS and M. A. FISHERKELLER

Argonne National Laboratory, Argonne, Ill.

```

procedure RES (n, c, alpha, mu, re, im, rt, gc) ; value n,
            c, alpha ; integer n, alpha ; integer array
            mu ; array c, re, im, rt, gc ;
comment RES finds simultaneously all zeros of a polynomial of
            degree n with real coefficients,  $c_j$  ( $j = 0, \dots, n$ ), where  $c_n$ 
            is the constant term. The real part,  $re_i$ , and imaginary part,
             $im_i$ , of each zero, with corresponding multiplicity,  $mu_i$ , and
            remainder term,  $rt_i$ , ( $i = 1, \dots, n$ ), are found and a poly-
            nomial with coefficients  $gc_j$  ( $j = 0, \dots, n$ ), is generated from
            these zeros. Alpha provides an option for local or nonlocal
            selection of M, the number of root-squaring iterations, and
            delta and epsilon, acceptance criteria. If alpha = 1, these
            parameters are assigned locally. If alpha = 2, M, delta and
            epsilon are set equal to the global parameters Mp, deltap,
            and epsilonp, respectively. In cases where zeros may be found
            more than once, the superfluous ones are eliminated by fac-
            torization. The method has been described by E. H. Bareiss
            (J. ACM 7, Oct. 1960, pp. 346-386). ;
