ALGORITHM 364

COLORING POLYGONAL REGIONS [Z]

ROBERT G. HERRIOT (Recd. 30 Jan. 1967, 31 Oct. 1968 and 2 July 1969)

University of Wisconsin, Computer Science Department,
Madison, WI 53706

KEY WORDS AND PHRASES: coloring polygonal regions, coloring planar surfaces, drawing pictures, shading enclosed regions

CR CATEGORIES: 4.9

procedure drawarea (*x*, *y*, *firstpoint*, *lastpoint*, *section*, *numrows*, *numseats*, *regcolor*, *paintflag*, *paintcolor*, *sgn*, *dir*, *edge*);
value *firstpoint*, *lastpoint*, *numrows*, *numseats*, *regcolor*, *paintflag*, *paintcolor*, *sgn*, *dir*, *edge*;
integer *firstpoint*, *lastpoint*, *numrows*, *numseats*, *regcolor*, *paintcolor*, *sgn*;
real *edge*;
Boolean *paintflag*, *dir*;
real array *x*, *y*;
integer array *section*;

comment This procedure is a part of a large program which produces the card stunts for the Stanford University football game half-times. The initial development was done by L. Breed, L. Tesler, and J. Sauter. The author (a Stanford student at the time) made many further developments on this program which included producing an algorithm for coloring in polygonal regions. Prior to the development of this algorithm, there were many cases which did not work. The larger program takes as input an English description of the stunts and produces as output an image of each flip (similar to a frame in a movie film), as a rectangle that has 45 rows with 77 seats in each row. The main program, which will be considered the driver program for the purpose of the procedure *drawarea*, does all of the handling of the definition of regions and also the printing of the images. It should be mentioned that the procedure *drawarea* in the actual program is just part of a larger procedure and that all of the parameters are global in order to increase efficiency. The purpose of *drawarea* is to take the current regions and draw them in the two-dimensional array *section*, which is to be declared as *section* [1: *numrows*, 1: *numseats*] (the array is 45 by 77 for Stanford). Each completed picture in *section* is then printed and also written out on tape. Another program later takes this tape and processes it to produce an instruction card for each student holding a set of colored cards in the routers section.

The larger program allows objects of any shape to be defined by a series of *x*, *y*-coordinates. It will accept a series of points which are given an identifying name by the user and which can then be used as (1) a group of points, (2) a series of connected line segments, (3) a polygonal region enclosed by the points (with the first and last point connected by a straight line). It also allows ellipses to be defined. Once an object is defined, it can be expanded and contracted in size, rotated about any fixed point, or moved anywhere, including all or partially out of sight. As soon as all objects are in place, the user can ask that an image of the picture be made. Except for polygonal regions, producing the image of these objects is trivial. The procedure

drawarea is the routine which places the polygonal regions in the array section.

The array *section* is presumed to have a background color associated with it. All objects, which also have an associated color, are then drawn into the array in a specified order so that the objects which are to be superimposed over other objects are drawn last. The procedure *drawarea* takes the coordinates of the point (which may not be integral) from arrays *x* and *y* with subscript values ranging from *firstpoint* to *lastpoint* and decides which seats in array *section* will form the left and right boundaries of this new region. After the boundary is determined, the interior must be colored in. The algorithm colors the region by taking each row and then examining each seat from left to right. For optimization, only the area of a minimal circumscribing rectangle is examined. At the beginning of each row the variable *count* is set to *leftcount* [*row*, 0] - *rightcount* [*row*, 0], which will be zero unless the object is partially out of sight on the left. Then as long as *count* remains zero, the seat is on the exterior and is not colored. As each seat is encountered, *leftcount* [*row*, *seat*] is added to *count*. When *count* is positive, the seat is in the interior or on a boundary and is colored. After each seat is processed, *rightcount* [*row*, *seat*] is subtracted from *count*. When *count* returns to zero, the seat is an exterior seat and is not colored. In any row it is possible to have the color turned on and off several times. Arrays *leftcount* and *rightcount* contain twice the number of left and right boundaries which pass through each individual seat. These two arrays solve the problem created by having several boundaries passing through one seat.

A further complication to the routine is added by allowing a region to be gradually changing color. Thus each region always has a color (*regcolor*) associated with it, and if the region is being swept with a new color, then *paintflag* is **true** and *paintcolor*, *sgn*, *dir*, and *edge* are used to determine the section of the region which is to be of the new color (*paintcolor*). The roles of the parameters for painting are: *sgn* and *dir* indicate the direction in which the imaginary paintbrush is moving. *dir* = **true** means the direction is horizontal and *dir* = **false** means vertical. *sgn* = -1 means the direction is left or down and *sgn* = 1 means the direction is right or up. *edge* is the row or seat (column) where the new color (*paintcolor*) ends and the old color (*regcolor*) begins. The driver program is expected to change *edge* with each new image so that the region looks as if it is being swept by a new color.

A related algorithm which determines whether a point is inside a polygon is presented in Algorithm 112 [1, 2].

This concurrent publication in Communications follows a policy announced by the Editors of the two departments in the March 1967 issue.

ALGORITHM 365

COMPLEX ROOT FINDING [C5]

H. BACH (Recd. 18 Apr. 1968 and 15 July 1969)

Laboratory of Electromagnetic Theory, Technical University of Denmark, Lyngby, Denmark

KEY WORDS AND PHRASES: downhill method, complex relaxation method, complex iteration, complex equation, transcendental complex equation, algebraic complex equation
CR CATEGORIES: 5.15

COMMENT. The present subroutine determines, within a certain region, a root of a complex transcendental equation $f(z) = 0$, on which the only restriction is that the function $w = f(z)$ must be analytic in the region considered. The iterative method used, the downhill method, was originally described in [2] and is discussed and modified in [1].

The program uses a complex function subprogram FUNC(Z) for the computation of $f(z)$. From a given complex starting point ZS, the iteration is performed in steps of initial length HS. The iterations stop at the root approximation ZE when either the function value DE at the end point is less than the prescribed minimum deviation DM or when the step length HE has become less than the prescribed minimum step length HM. For reference, the subroutine also returns DS, the function value at the starting point ZS, and N, the number of iterations used. There are thus four input parameters, namely the starting point ZS, the initial step length HS, the minimum step length HM, and the minimum deviation DM.

ACKNOWLEDGMENT. Thanks are due to Mr. Frank Jensen, M.Sc., who helped in the testing of this algorithm.

procedure regressor (*vec*, *kobs*, *levs*, *code*, *kfac*, *nfac*, *ndf*);
value *nfac*;
integer *kobs*, *levs*, *code*, *kfac*, *nfac*, *ndf*;
real *vec*;

comment The mathematical basis of the algorithm which forms the kernel of a very general analysis of variance and covariance procedure (Algorithm 367) is set out in [5, 6]. An overwhelming majority of the experimental designs in [2] may be analyzed in this way. Statistical nomenclature is given in parentheses.

A vector *vec*, of *nobs* elements (*observations*) traced by *kobs*, is replaced by *ndf* ≤ *nobs* elements (*regression coefficients*) obtained by the matrix product $C^T \cdot \text{vec}$, since the matrix is semiorthogonal. The number of initial elements is implied as the product of the *nfac* values of the variable *levs* which are traced by *kfac*. Values of *code*, similarly traced, specify matrices which enter a direct product [4] to form the transforming matrix C^T (*independent variates transposed*). As *code* takes the values 0, 1, or 2, the matrices selected are *I*, *j*, or *V*, i.e. the unit matrix of order *levs*, the unit vector of *levs* equal elements, or a matrix made up of *levs* - 1 mutually orthogonal unit vectors which are also orthogonal to the previous vector ($V^T \cdot j = 0$ and $V^T \cdot V = I$). A direct product of the transposes of the selected matrices forms the transforming matrix. An example of an actual call is shown to illustrate tracing: *example: regressor (vec[kobs], kobs, levskfac, code[kfac], kfac, nfac, ndf)*.

The squared length of the resultant vector (*sum of squares on ndf degrees of freedom*) is equal to the squared length of the projection of the original vector in the subspace spanned by an idempotent symmetric matrix (*idix*) *P*. Eigenvectors associated with unit eigenvalues of this projection operator [1] comprise the rows of the transforming matrix.

$$l^2 = \text{vec}^T \cdot P \cdot \text{vec} = \text{vec}^T \cdot C \cdot C^T \cdot \text{vec}. \quad (1)$$

The cosine of the angle between two similarly transformed vectors (*correlation coefficient*) is obtained in an analogous manner from a scalar product (*sum of cross products*).

$$l_{\text{vec}1\text{vec}2} \cos(\theta) = \text{vec}^T \cdot P \cdot \text{vec}. \quad (2)$$

Prior evaluation of direct products is very wasteful of operations [3], and use is made of an identity which involves ordinary (·) and direct (×) products:

$$(A \times B \times C) \cdot y = (A \times I \times I) \cdot (I \times B \times I) \cdot (I \times I \times C) \cdot y. \quad (3)$$

Although shown for a triple product the identity obviously holds for any number of factors. The identity, however, is only valid for square matrices and the rectangular *j* or *V* factors must therefore be bordered by zeros to satisfy. In the algorithm multiplication by these zeros is bypassed, and after each transformation the vector is packed ready for the next.

Another identity:

$$(A \times B) \cdot (C \times D) = (A \cdot C) \times (B \cdot D), \quad (4)$$

implies that the ordinary products in (3) may be taken in any order, since the direct product factors commute. The transformations should therefore be taken in the order which achieves the largest reduction in the number of elements. Since *j*-factors achieve a reduction in the ratio *levs*:1, while *V*-factors merely

achieve $levs:levs - 1$, the transformations are arranged in descending order of levels for j -factors followed by an ascending order of levels for V -factors. Transformations requiring the unit matrix are, of course, skipped.

comment The algorithm provides analyses of variance, covariance, and regression for data collected according to a wide variety of experimental designs. The vector of elements comprising either a response (*y* or *dependent*) or a treatment (*x* or *independent*) variate forms a conceptual complete array of *nfac* dimensions. The implied subscripts are a set of discrete variables which define an error classification. Designs of this type include the *fully randomized*, *randomized block*, *incomplete block*, *split (to any order) plot*, *Latin (and higher) squares*, *lattices*, et cetera, and make up the overwhelming majority in use [3]. By means of an appropriate transformation the frequency data of contingency tables may be processed to provide partitions of chi-square [1]. A comprehensive account of the mathematical basis is given in [4, 5].

In this implementation extensive use is made of the *call-by-name* facility so that generators and routines involving auxiliary store may freely be used for all input variables. Usually data sets are quite small and storage of intermediate quantities within the immediate access store is possible. In the following notes on the formal parameters relevant tracer variables are shown in brackets. An arrow ($\rightarrow$) indicates that the variable is used only as a source of information.

balanced anova: If the projection of *x*-variate numbered *jtrt* has a correlation coefficient exceeding *tolcor* with the projection of *x*-variate numbered *klrt* in subspace *ispace* of the design, then abnormal termination is forced with *balanced anova* = $10^8 \times \text{ispace} + 10^8 \times \text{jtrt} + \text{klrt}$. Zero is returned as the value of the procedure in the case of normal termination. Note that this time-consuming check of the *balance* of the treatment model with respect to the error model is only performed if *check diagonality* is set **true**.

***y*, *missing y* [*ires*, *iobs*] $\rightarrow$:** The *y*-variate generator or array must provide trial values, e.g. the average of present elements for the variate, for any missing data. These elements are flagged by **true** in the **Boolean** *missing y* which may take the form of an expression in terms of *ires*, *iobs*, and **integer** constants.

***x* [*ilrt*, *iobs*] $\rightarrow$:** A complete specification of the orthogonal decomposition of the total sum of squares (and products) using polynomials or some other form of contrast representation is required. In the case of treatment classifications (for example *factorial experiment*) the *x*-variate values may be generated as a direct product (or as a selection of elements from such a matrix) of a number of small contrast matrices, i.e. orthogonal matrices with first column having elements greater than zero (usually constant).

***fixed effect* [*ilrt*, *ispace*] $\rightarrow$:** By setting this variable **true** the flagged regression coefficients, i.e. *beta* number *ilrt* in estimation subspace number *ispace*, are declared to be error free or invariants. In most practical cases this facility is only relevant to the constant term of the regression model.

***estimate* [*ilrt*, *ispace*] $\rightarrow$:** By setting this variable **false** the flagged regression coefficients are declared to be zero and are not estimated in the indicated subspaces. Usually this facility is not required, and the constant **true** is used as actual parameter.

***error level* [*ifac*] $\rightarrow$:** The variable sets the number of levels of the error classifications. If it is assumed that the conceptual subscripts have unit lower bounds, then the upper bounds are set. Variates (traced by *iobs*) must be in lexical order by the implied subscripts, and use of a permutation array or function may be required to achieve this end.

***error code* [*ifac*, *ispace*] $\rightarrow$:** Error sources of variation (estimation or error subspaces) are specified by integer codes 0, 1, or 2. The codes could be generated by means of a procedure which interpreted a string of input characters denoting the *error structure* of the experimental design, see [4, 5]. A set of *nfac* integers specifies a projection operator which spans a subspace. The operator is formed as the direct product of (0) *identity matrix* *I*, (1) *averaging matrix* *J*, or (2) *differencing matrix* *K* = *I* - *J*. Every element of the averaging matrix is equal to the reciprocal of the order,

e.g.: $2, 0, 1, 2, 1 \leftrightarrow K_1 \times I_2 \times J_3 \times K_4 \times J_5 = P_i$, say.

It is required that the error subspaces be mutually orthogonal, $P_i P_j = \delta_{ij} P_i$.

Code Sets for Some Common Designs

Design	Codes						$P_1 + P_2$
Fully randomized	1	2					0
Randomized or incomplete block	11	21	02				01
Split plot	111	211	021	002			011
Split split plot	1111	2111	0211	0021	0002		0111
Square or rectangle	11	21	12	22			01
Revoluted square or rectangle	111	211	021	012	022		011
Three-way crossed error	111	211	121	112	221	212 122 222	011

In certain circumstances it may be desired to work $\text{mod}(J \times J \times \dots \times J)$, that is the *y*-variables are adjusted to have zero mean. In this case the first code is omitted from the analysis. Usually it is convenient to pool the subspaces defined by $J \times J \times \dots \times J$ and $K \times J \times \dots \times J$ yielding (by addition) $I \times J \times \dots \times J$, and if this is required the first two columns of the table are replaced by the rightmost auxiliary column.

***all y* [*ires*], *all x* [*ilrt*], *length y* [*ires*, *ispace*], *length x* [*ilrt*, *ispace*]:** The lengths of the *y*, *x*, projected *y*, and projected *x* vectors are returned. Null variates (which have zero length) should be indicated in, or excluded from, analysis of variance tables (et cetera) derived from an activation of the procedure.

***pooled beta*, *se beta* [*ires*, *ilrt*]:** The weighted mean regression coefficient relating *y*-variate number *ires* to *x*-variate number *ilrt* is returned in *pooled beta*, and the standard error of the estimate in *se beta*.

***normalized beta* [*ires*, *ilrt*, *ispace*]:** Within each subspace the regression coefficients are scaled so that it may be assumed that the sum of squares of each (nonnull) projected *x*-variate is unity. The *dyad* obtained by forming all pairwise products over the tracer *ires* (fixing the other tracers) is a single degree of freedom contribution due to treatment (*x*-variate) number *ilrt* to subspace number *ispace* of the analysis of variance (and covariance if *nres* > 1).

***error* [*ires*, *jres*, *ispace*]:** For each subspace an error covariance matrix is computed. This is the only variable bearing the tracer *jres* which is constrained so that *jres* $\leq$ *ires*. The calling program may make provision to pack the matrices in triangular form using a subscript function: *pack*[*ires*] + *jres*, where *pack*[*ires*] = (*ires* × (*ires* - 1)) ÷ 2.

***df total*, *df error* [*ispace*]:** The variables return the total and error degrees of freedom for each subspace.

***tolcor*:** If the activation calls for a check of the orthogonality of projected *x*-variables, then this constant sets the value of the correlation coefficient, which should not be exceeded in the test.

tolength: A projected vector is assigned zero length if the ratio of the computed length to that of the unprojected vector, multiplied by the square root of the ratio of the number of observations to degrees of freedom of the subspace, fails to exceed this criterion.

tolmpss: As a single measure of all missing data a sum of squares is computed. If the ratio of the absolute value of the difference between this sum and that of the previous iteration (or 0), to the current sum, fails to exceed this constant, no further iterations are made.

ispace, nspace, ires, jres, nres, irlt, nrlt, iobs, nobis, ifac, nfac: The identifiers with initial letter *i* or *j* are tracers mnemonically related to the remaining identifiers which define the number of subspaces, *y*-variables, *x*-variables, observations and error factors, respectively.

max cycle: An upper limit to the number of iterations required for the convergence of estimates of missing data is provided by this parameter.

check diagonality: If this parameter is **true** then the projected *x*-variables are checked for orthogonality. While computing time is saved by the opposite setting, incorrect results are computed if an invalid assumption of orthogonality is made.

projector: In order to compute the consequences of projection of variates, a choice between at least two procedures is made: $P \cdot x = C \cdot C^T \cdot x$ or $C^T \cdot x$. The idempotent symmetric projection operator P (see [4, 5]), or the rectangular matrix made up of the eigenvectors corresponding with unit eigenvalues (see [2]) is used. The second alternative is preferred since the transforming matrix is then thin, and Algorithm 366 is an implementation of this approach.

putpy, getpy, putpx, getpx: These procedures are concerned with the transmission of transformed variates between arrays internal to the algorithm and auxiliary store. While immediate access store may be used as auxiliary store with small problems, backing media such as magnetic drum, disk, or tape are required for large problems. The procedure *putpy* transmits all *nelm* elements of a transformed *y*-variate to auxiliary store, while *getpy* performs the reverse transmission. Similar actions on the *x*-variables are carried out by the other two procedures. All four routines have similar calling sequences: (*vec[ielm]*, *ielm*, *nelm*, *ivar*, *ispace*), where *vec* identifies the vector to be moved, *ielm* traces the elements of the vector, *nelm* (returned by *projector*) specifies the number of elements to be moved, *ivar* gives the variate number, and *ispace* gives the subspace number. The elements to be moved are in the leading position in *vec*, and an appropriate instruction begins **for ielm := 1 step 1 until nelm do**. The last two formal parameters may be used to index an array listing the starting positions of the vectors in auxiliary storage.

CERTIFICATION OF ALGORITHM 147 [S14]
 PSIF [D. Amit, *Comm. ACM* 5 (Dec. 1962), 605]
 RONALD G. PARSONS* (Reed. 7 Dec. 1966 and 5 Aug.
 1969)

Stanford Linear Accelerator Center, Stanford University,
 Stanford, CA 94305

* Present address: Department of Physics, The University of
 Texas, Austin, TX 78712. Work supported by the US Atomic
 Energy Commission.

KEY WORDS AND PHRASES: gamma function, logarithmic
 derivative, factorial function, psi function
 CR CATEGORIES: 5.12

The following errors were noted in this algorithm in addition
 to those noted by Thacher [2].

- (4) in the comment should read "For $-x < -1$ we use: (4)
 $\Psi(-x) = \Psi(x-1) + \pi \cot(\pi x)$ ".
- At the end of the first comment add: "Note that $\text{psif}(x) \equiv$
 $\Psi(x)$ is $\psi(x+1)$ as defined, for example, by Jahnke-Emde-Lösch"
 (see [1]).

c. The statement in the algorithm before the label *pos* should read: $\text{psi} := \text{pei} \times \cos(\text{pei} \times x) / \sin(\text{pei} \times x)$; These errors caused the procedure to give incorrect results for $\text{psif}(x, a)$ for $x < -1$.
d. The arguments *tan* and *ln* should be deleted from the parameter list and **real procedure** *tan*, *ln*; should be deleted from the specification part of the procedure heading.

With these changes and those of Thacher, the procedure was translated into Burroughs B5500 extended ALGOL and run on the Stanford B5500. $\text{psif}(x, a)$ was tabulated for $x = -2.9(0.1)5.0$ with $a = 8.0$. The results agreed with tabulated values to within $1/(240a^8)$.

CERTIFICATION OF ALGORITHM 229 [B1] ELEMENTARY FUNCTIONS BY CONTINUED FRACTIONS [James C. Morelock, *Comm. ACM* 7 (May 1964), 296]

T. A. BRAY (Recd. 18 June 1964)

Boeing Scientific Research Laboratories, Seattle, WA 98124

KEY WORDS AND PHRASES: continued fractions, Padé table

CR CATEGORIES: 5.19

Algorithm 229 was coded in FORTRAN II and run on the IBM 1620 computer for $x = 0.50$ and 0.75 , for $n = 1, 2, 3, 4$, and for $\text{parm} = 1, 2, 3, 4, 5, 6, 7$.

For $x = 0.50$ my values agree with the author's up to $\pm 10^{-11}$.

For $x = 0.75$ and $n = 4$, my values of $\sin x$, $\cos x$, $\tan x$, and $\exp x$ agree with tabulated values to within $\pm 10^{-11}$. For the same x and n my values of $\sinh x$, and $\cosh x$, and $\tanh x$ agree with tabulated values to within $\pm 10^{-10}$; no tables were available to check the 11th decimal.

REMARK ON ALGORITHM 300 [S22] COULOMB WAVE FUNCTIONS [J. H. Gunn, *Comm. ACM* 10 (Apr. 1967), 244]; CERTIFICATION OF ALGORITHM 300 [K. S. Kölbig, *Comm. ACM* 12 (May 1969), 279]

K. S. KÖLBIG (Recd. 14 Apr. 1969)

Data Handling Division, European Organization for Nuclear Research (CERN), 1211 Geneva 23, Switzerland

KEY WORDS AND PHRASES: Coulomb wave functions, wave functions, special functions, function evaluation

CR CATEGORIES: 5.12

Recently, Isacson [1] pointed out that the coefficient of $\eta^{-16/8}$ in the known asymptotic expansion for the irregular Coulomb wave function $G_0(\eta, \rho)$ on the transition line $\rho = 2\eta$ was erroneous.

In addition, he gave the expansions for F_0 , G_0 , F_0' and G_0' up to order η^{-8} , whereas the old expansions were given to order $\eta^{-16/8}$ only.

Therefore, and for reasons of speed, the relevant part of Algorithm 300 should be changed as follows:

```
begin comment G[0] and Gd[0] are calculated on the transition
line for rhom = 2 × eta, ref. Isacson in remark;
array el[1:12]; real et1;
et[1] := eta ↑ (−2/8);
```

```
for i := 2 step 1 until 12 do et[i] := et[1] × et[i−1];
et1 := eta ↑ (1/8);
G[0] := 1.223404016 × et1 × (1 + 0.04959570165 × et [2]
− 0.008888888889 × et [3] + 0.002455199181 × et [5]
− 0.0009108958061 × et [6] + 0.0008453619999 × et [8]
− 0.0004096926351 × et [9] + 0.0007116506205 × et [11]
− 0.00002439615603 × et [12]);
Gd[0] := (−0.7078817734/et1) × (1 − 0.1728260369 × et [1]
+ 0.0003174603174 × et [3] − 0.003581214850 × et [4]
+ 0.0003117824680 × et [6] − 0.0009073966427 × et [7]
+ 0.0002128570749 × et [9] − 0.0006215584171 × et [10]
+ 0.00003685244766 × et [12]);
rhom := 2 × eta
```

end;

Furthermore, it was found in this connection that replacing the first line of the fourth *if* statement of the algorithm by

```
if eta < 4 ∧ eta < rho/2 then
```

gives, together with the above expansions, better results for $\rho = 2\eta$ in test (iii) and for $\rho = 3$, $\eta = 5$ in test (i) of the Certification.

The relevant statements in test (iii) of the Certification should therefore be replaced by the following ones:

$F_0 - 1$ unit for $\rho = 5$, $\rho = 6$, and $\rho = 8.5$.

$F_0' - 1$ unit for $\rho = 6$.

$G_0 - 1$ unit for $\rho = 5.5$, $\rho = 16$, and $\rho = 30$.

$G_0' - 1$ unit for $\rho = 5.5$.

REMARK ON ALGORITHM 341 [H] SOLUTION OF LINEAR PROGRAMS IN 0-1 VARIABLES BY IMPLICIT ENUMERATION [J. L. Byrne and L. G. Proll, *Comm. ACM* 11 (Nov. 1968), 782]

L. G. PROLL (Recd. 5 Dec. 1968 and 18 Aug. 1969)

University of Southampton, Department of Mathematics, Hampshire, England

KEY WORDS AND PHRASES: linear programming, zero-one variables, partial enumeration

CR CATEGORIES: 5.41

The published algorithm contains an error in the assembly of the initial partial solution, *s*, if a priori information is given. In certain cases this can cause premature termination of the algorithm. The error may be corrected by replacing the following lines of the procedure body, from

```
begin
for j := 1 step 1 until n do
to
e := n; z := A[0, 0]; go to L0;
by
```

```
begin
e := 0;
for j := 1 step 1 until n do
if x[j] = 0 then v[j] := 0
else
begin
e := e + 1; s[e] := j; v[j] := 3;
for i := 1 step 1 until m do
A[i, 0] := A[i, 0] + A[i, j];
end;
z := A[0, 0]; go to L0;
and by deleting the line
if api then begin api := false; go to L4 end;
```

Key. The first column, A1, B1, C1, is the key to the classification system categories; second column: number of the algorithm if in CACM; third column: algorithm title; fourth column: month, year, pages (in parentheses) in CACM or reference elsewhere. This 1969 index is the first supplement to the Index by Subject to Algorithms, 1960-1968 (*Comm. ACM* 11, 12 (Dec. 1968), 827-830).
